Roadmap

1. Model explanation and calibration

2. Benchmarking the costs: CBD shift

3. Model of a public-sector move

4. Reduced-form evidence

Model: Workers choose where to live and where to work

Worker o living in i, working in j:

$$u_{ijo} = \frac{B_i \, w_j \, z_{ijo}}{Q_i^{1-\beta} \, e^{\kappa \tau_{ij}}}$$

- B_i residential amenity, Q_i rent price, $1 - \beta$ housing share
- τ_{ij} travel time (minutes), κ commute cost parameter
- z_{ijo} taste draw, Fréchet with dispersion ε

Model: Workers choose where to live and where to work

Worker o living in i, working in j:

$$u_{ijo} = \frac{B_i \, w_j \, z_{ijo}}{Q_i^{1-\beta} \, e^{\kappa \tau_{ij}}}$$

- B_i residential amenity, Q_i rent price, $1 - \beta$ housing share
- τ_{ij} travel time (minutes), κ commute cost parameter
- z_{ijo} taste draw, Fréchet with dispersion ε

$$\text{Share choosing } i,j \;=\; \frac{\left(\dfrac{B_i \, w_j}{Q_i^{1-\beta} \, e^{\kappa \tau_{ij}}} \right)^{\varepsilon}}{\sum_{r,s} \left(\dfrac{B_r \, w_s}{Q_r^{1-\beta} \, e^{\kappa \tau_{rs}}} \right)^{\varepsilon}}, \qquad \nu = \varepsilon \kappa$$

Model: Firms, builders and spillovers

- **Firms:** Produce with labour L_{Fj} and floorspace H_{Fj}, with productivity A_j

$$Y_j = A_j L_{Fj}^{\alpha} H_{Fj}^{1-\alpha}$$

Model: Firms, builders and spillovers

- **Firms:** Produce with labour L_{Fj} and floorspace H_{Fj}, with productivity A_j

$$Y_j = A_j L_{Fj}^{\alpha} H_{Fj}^{1-\alpha}$$

- **Builders:** $H_i = \psi_i Q_i^{\zeta}$, construction productivity ψ_i, supply elasticity ζ

Model: Firms, builders and spillovers

- **Firms:** Produce with labour L_{Fj} and floorspace H_{Fj}, with productivity A_j

$$Y_j = A_j L_{Fj}^{\alpha} H_{Fj}^{1-\alpha}$$

- **Builders:** $H_i = \psi_i \, Q_i^{\zeta}$, construction productivity ψ_i, supply elasticity ζ

- **Spillovers:** Nearby jobs raise productivity, nearby residents raise amenity

$$A_j = a_j \left(\sum_s e^{-\delta \tau_{js}} \frac{L_{Fs}}{K_s} \right)^{\lambda} \qquad B_i = b_i \left(\sum_s e^{-\rho \tau_{is}} \frac{L_{Rs}}{K_s} \right)^{\eta}$$

- L_F jobs, L_R residents
- λ, η spillover strength; δ, ρ decay with travel time
- a_j, b_i: each place's fundamentals

Data and parameters

- **Residents, jobs and incomes:** 2016 Census, aggregated to 4,965 hexagons (400 m)
- **Land values:** valuations for land tax, parcel level, 2016
- **Travel times:** fastest travel time over the 2016 road network
- **Housing share** $1 - \beta = 0.30$: household expenditure survey
- **Spillovers** $\lambda,\ \delta,\ \eta,\ \rho = .07,\ .36,\ .15,\ .76$: Ahlfeldt et al. (2015)
- **Floorspace supply elasticity** $\zeta = 1.86$: Combes, Duranton & Gobillon (2021); consistent with Sydney's land value–rent elasticity

Calibration: Invert the model at Sydney's 2016 equilibrium

- **Commuting decay** ν = 0.126: regressing 2016 commuting flows on travel time
- **Taste dispersion** ε = 6.2: dispersion of observed vs. adjusted wages
- **Invert the equilibrium conditions to calibrate fundamentals:**
  - many residents despite high rents and poor job access $\Rightarrow$ high amenity
  - many workers despite high rents, wages and poor worker access $\Rightarrow$ high productivity

Jobs re-form around Parramatta and drain from the rest of the city

Counterfactual / baseline employment per hexagon, log scale. Outside the swapped sets jobs fall 20%; 4.5% of hexagons gain.

Concentration →

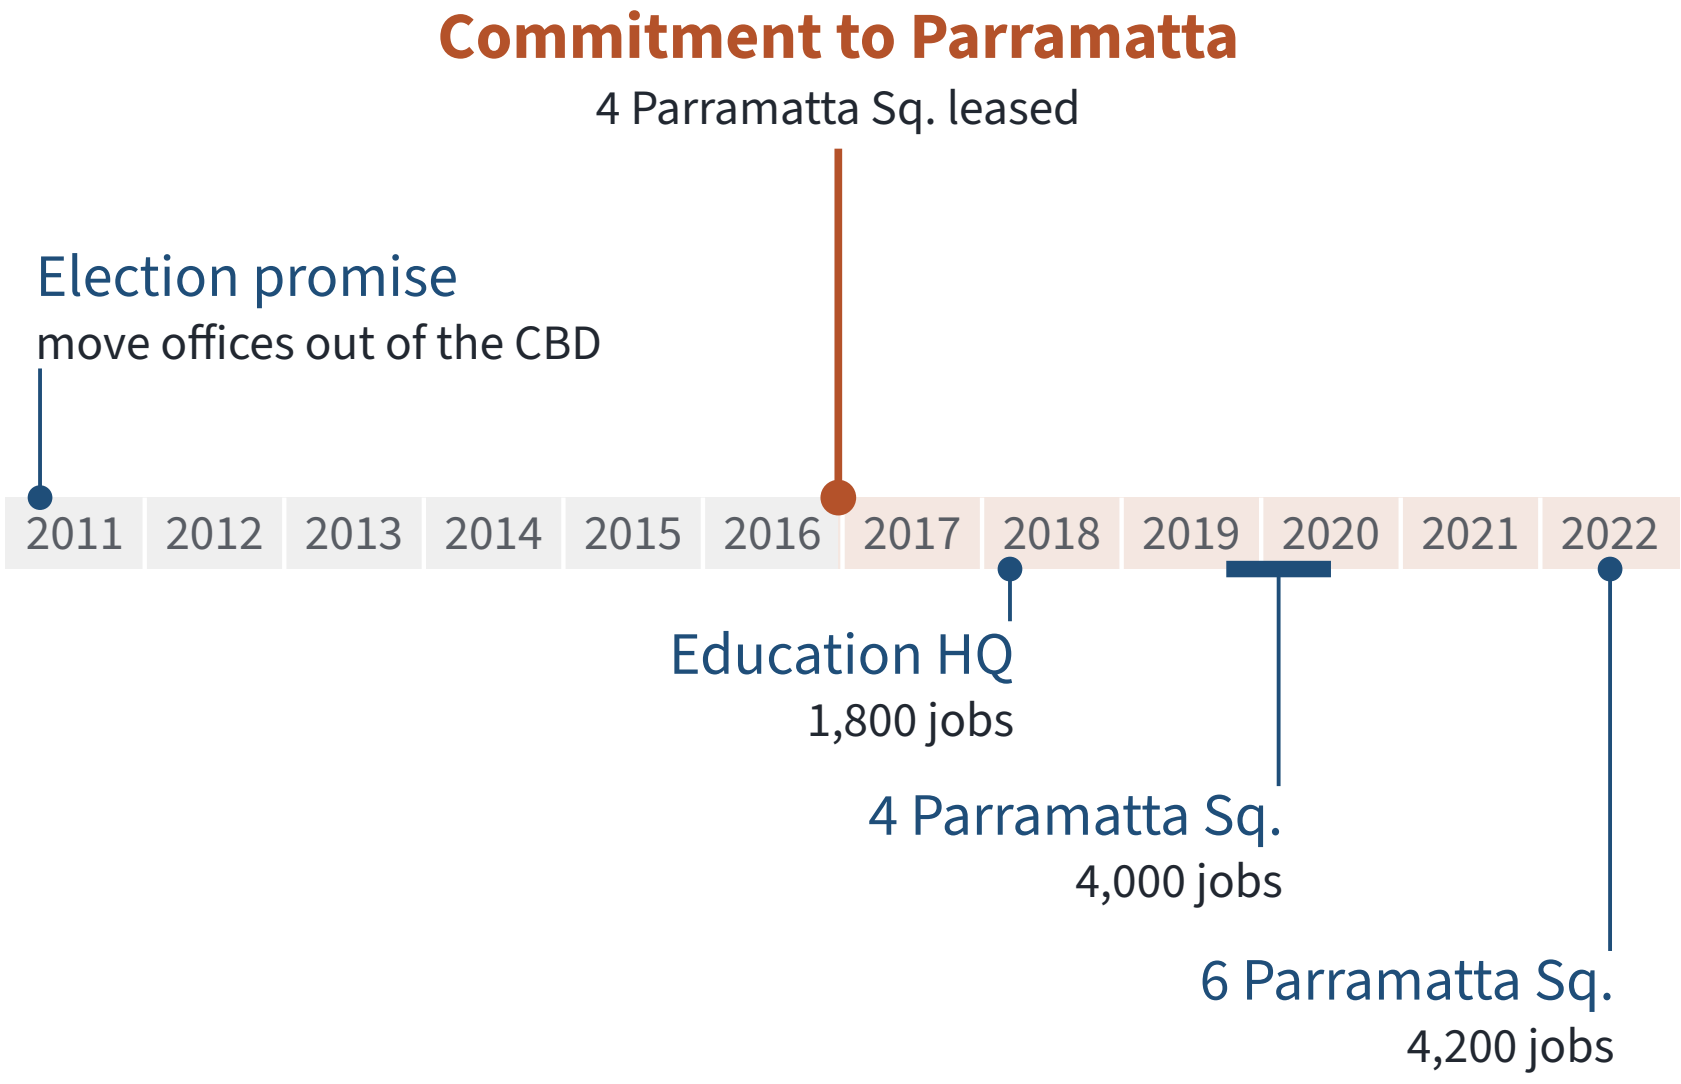

1. Model explanation and calibration

2. Benchmarking the costs: CBD shift

3. Model of a public-sector move

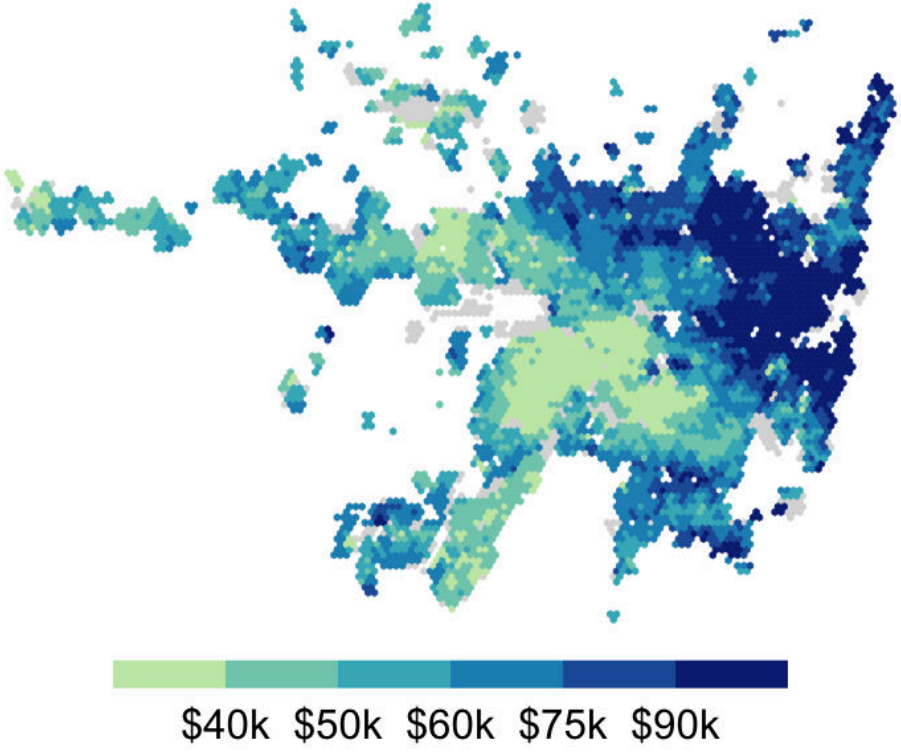

4. Reduced-form evidence

The policy: ∼10,000 public-sector jobs moved to Parramatta, 2018–22

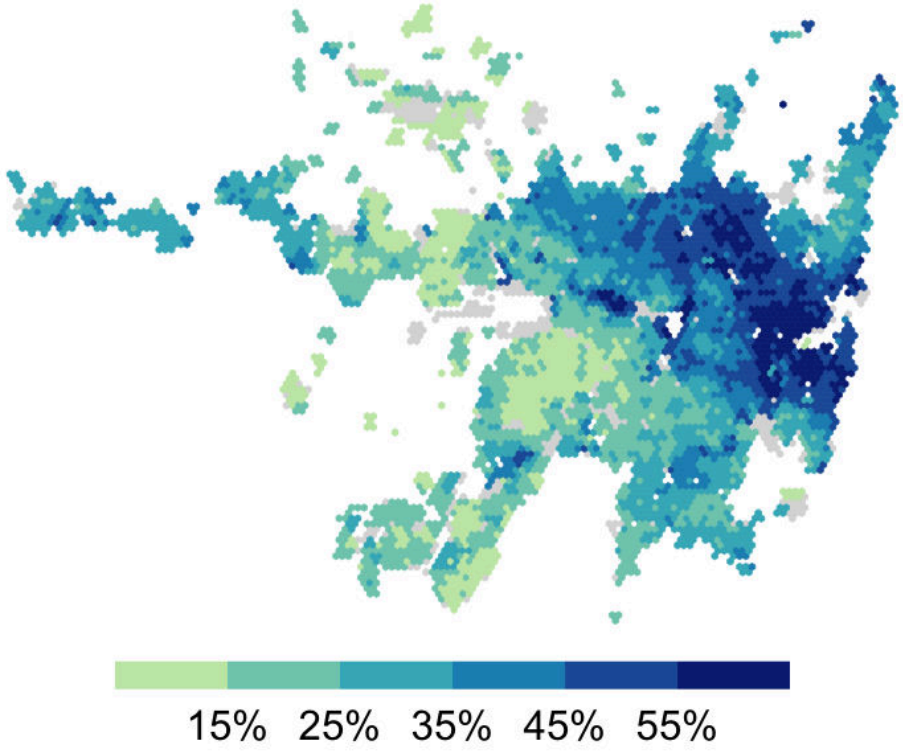

High earners and graduates live in the east

Mean personal income

Share of graduates

By home location, residents aged 15+, on the model's 400 m hexagons. Income: residents with a positive income. Graduates: bachelor's degree or higher. Grey: under 20 residents. 2016 Census.

Adding a public sector and worker types to the model

- **Public sector:** government places its offices
  - wages set centrally; offices rent floorspace like any firm
- **Two types** t: graduates (h), non-graduates (l); own amenities, commuting costs, housing shares
- **One firm per location** hires both types:

$$Y_j = L_{Fj}^{\alpha} H_{Fj}^{1-\alpha}, \qquad L_{Fj} = \left[\sum_t \left((A_j^t)^{1/\alpha} L_{Fj}^t \right)^{\frac{\sigma-1}{\sigma}} \right]^{\frac{\sigma}{\sigma-1}}$$

A_j^t: productivity of type-t workers L_{Fj}^t; $\sigma = 1.4$: substitution elasticity

$\rightarrow$ *more productive graduates lift nearby non-graduates' wages*

The key unknown: do public workers make nearby private firms more productive?

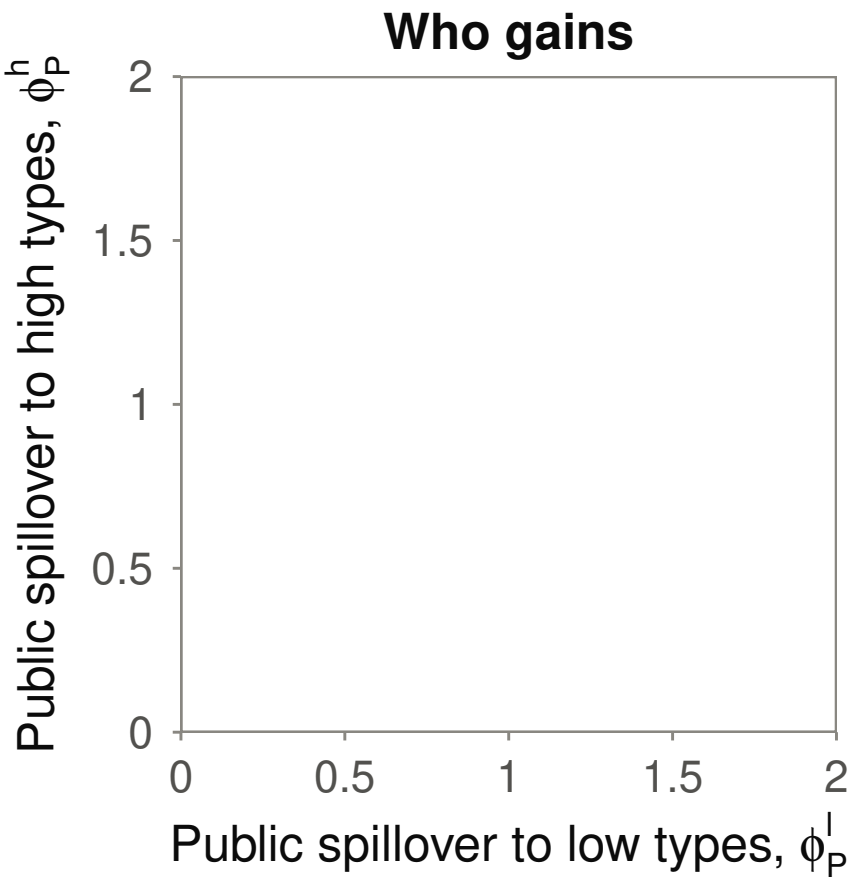

$$A_j^t = a_j^t \left(\sum_s e^{-\delta \tau_{js}} \frac{L_{Fs} + \phi_P^t L_{PFs}}{K_s} \right)^{\lambda}$$

- t: graduate (h) or non-graduate (l) firms; L_F: private jobs; L_{PF}: public jobs
- ϕ_P^t: weight a type-t firm puts on a public neighbour, relative to a private one

$\phi_P^t = 0$: public offices are just tenants
$\phi_P^t = 1$: a public worker is as good a neighbour as a private one

$\rightarrow$ *no direct estimate exists: I show results across* $\phi_P^h, \phi_P^l \in [0, 2]$

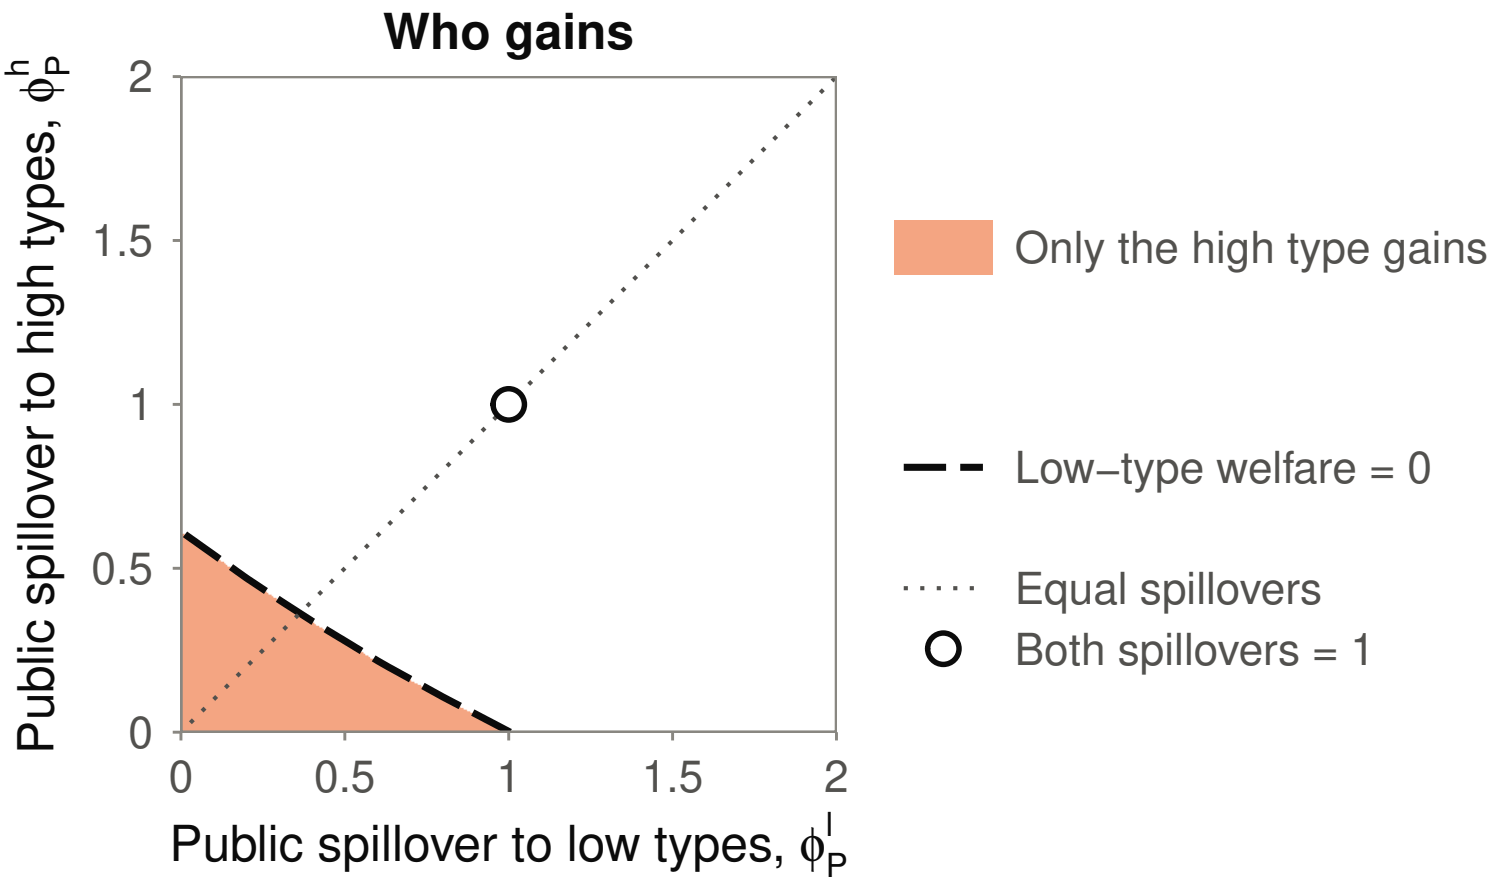

Who gains depends on the public→private spillover

2. Benchmarking the costs: CBD shift

3. Model of a public-sector move

4. Reduced-form evidence

Synthetic control: data and outcome

- **Data:** the universe of NSW land values (Valuer General), 2012–25
- **Outcome:** land value per m^2 in 800 m-radius circles around each centre
- Calculated from a fixed panel of commercially zoned parcels

Synthetic control: the estimator

- **Synthetic Parramatta:** a weighted blend of the other centres j

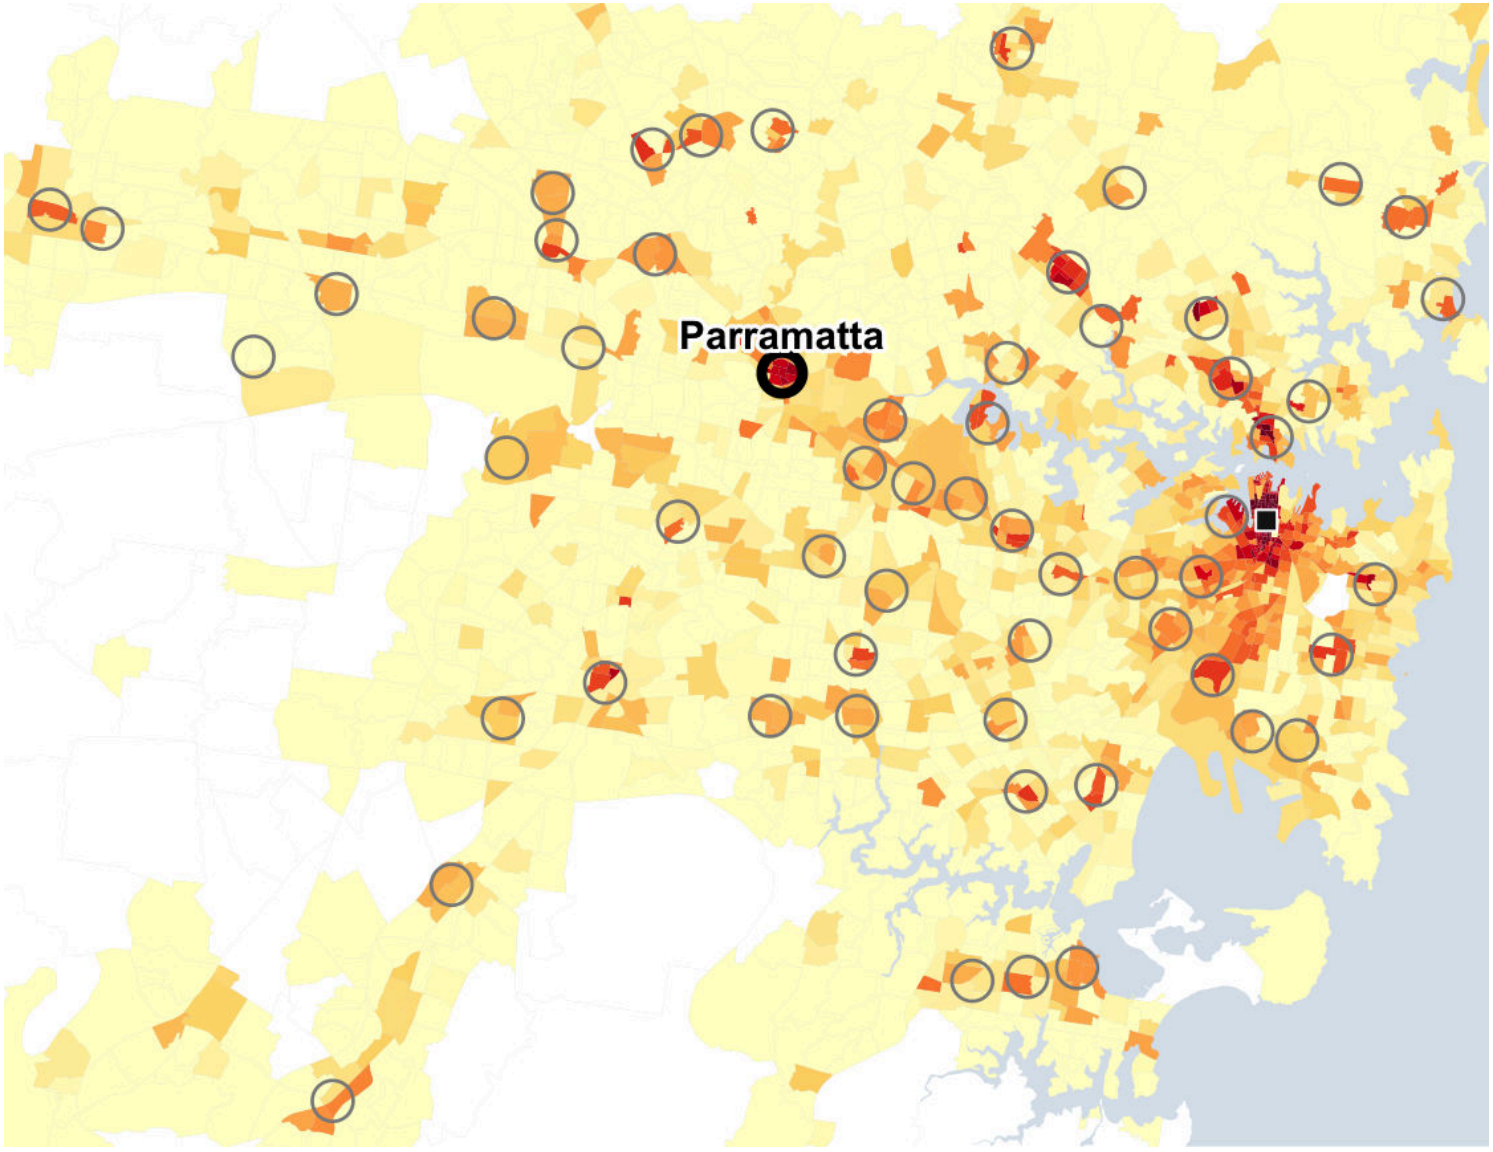

$$Y_t^{\text{synth}}(w) = \sum_j w_j \, Y_{jt}, \qquad w_j \geq 0, \quad \sum_j w_j = 1$$

- **Fit:** weights minimise the gap over the pre-period, 2012–16

$$w^* = \arg\min_w \sum_{t=2012}^{2016} \left(Y_{Pt} - Y_t^{\text{synth}}(w) \right)^2$$

- **Tie-break $\hat{w}$:** the most similar donors, within 1 pp of level of the best fit
- **Effect:** the gap after the Dec 2016 lease, $\hat{\alpha}_t = Y_{Pt} - Y_t^{\text{synth}}(\hat{w})$, $t \geq 2017$
- **Placebo inference:** each donor as if treated — is Parramatta's gap extreme?

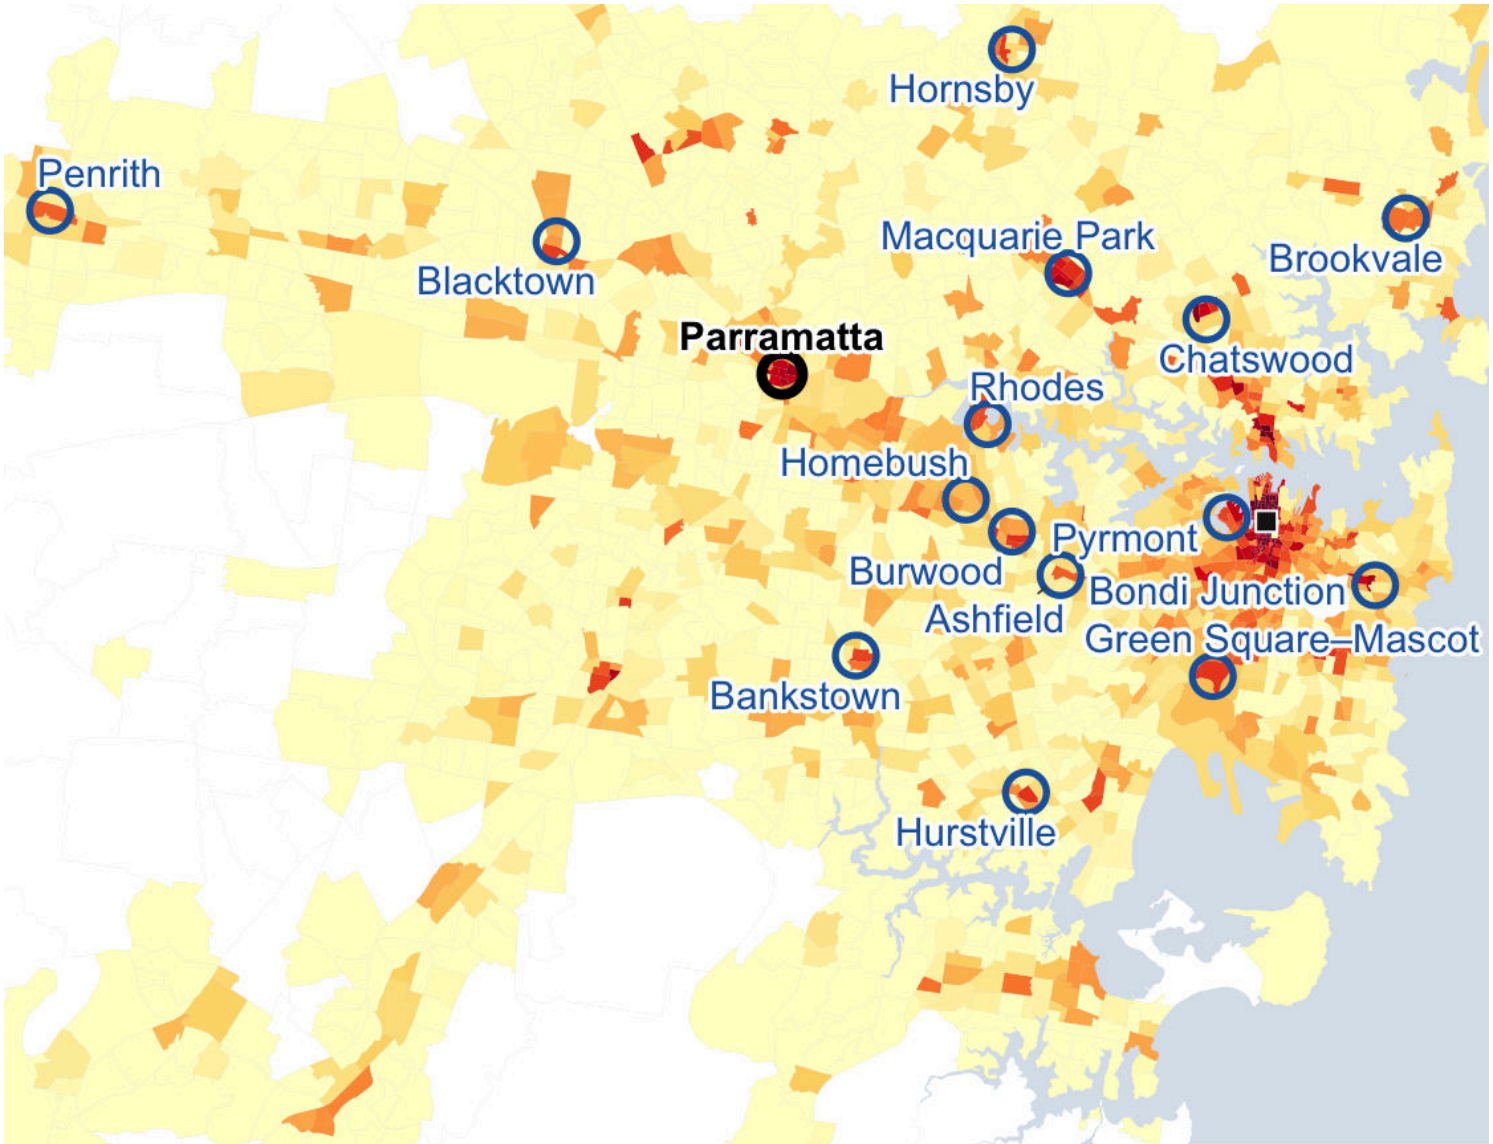

The candidates: Sydney's employment centres

800 m circles over 2016 jobs per km^2; ■ = CBD.

The screens →

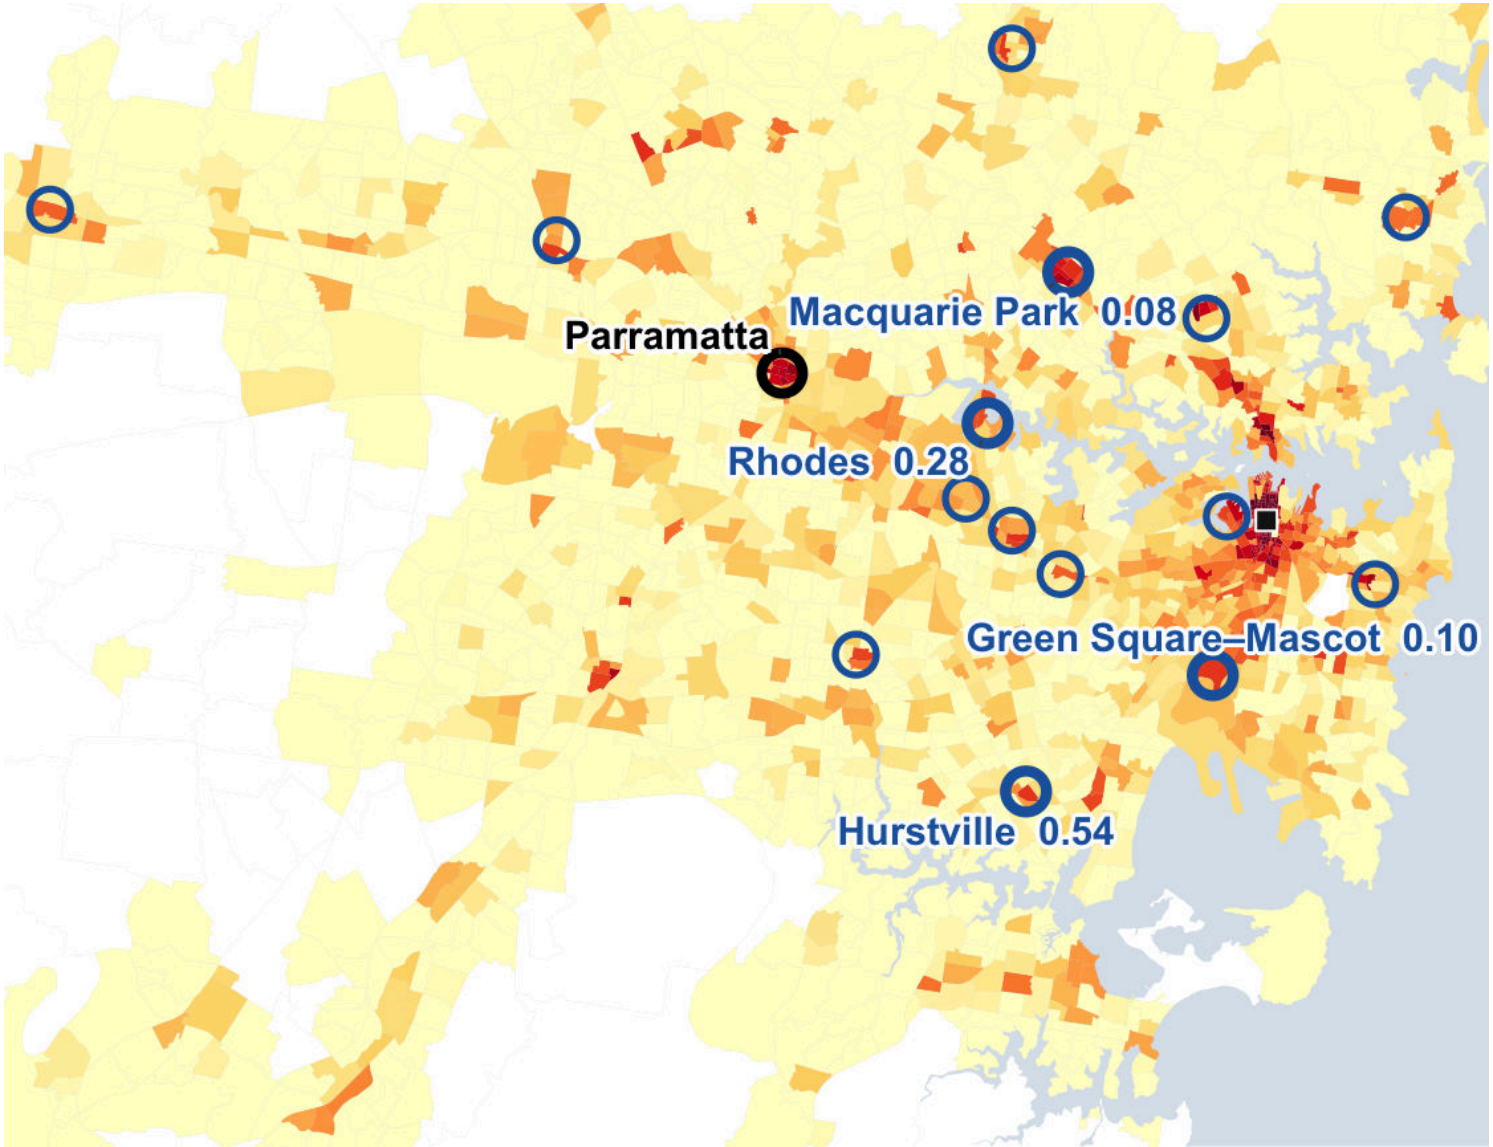

Choose the 15 most similar centres

800 m circles over 2016 jobs per km^2; ■ = CBD.

The screens →

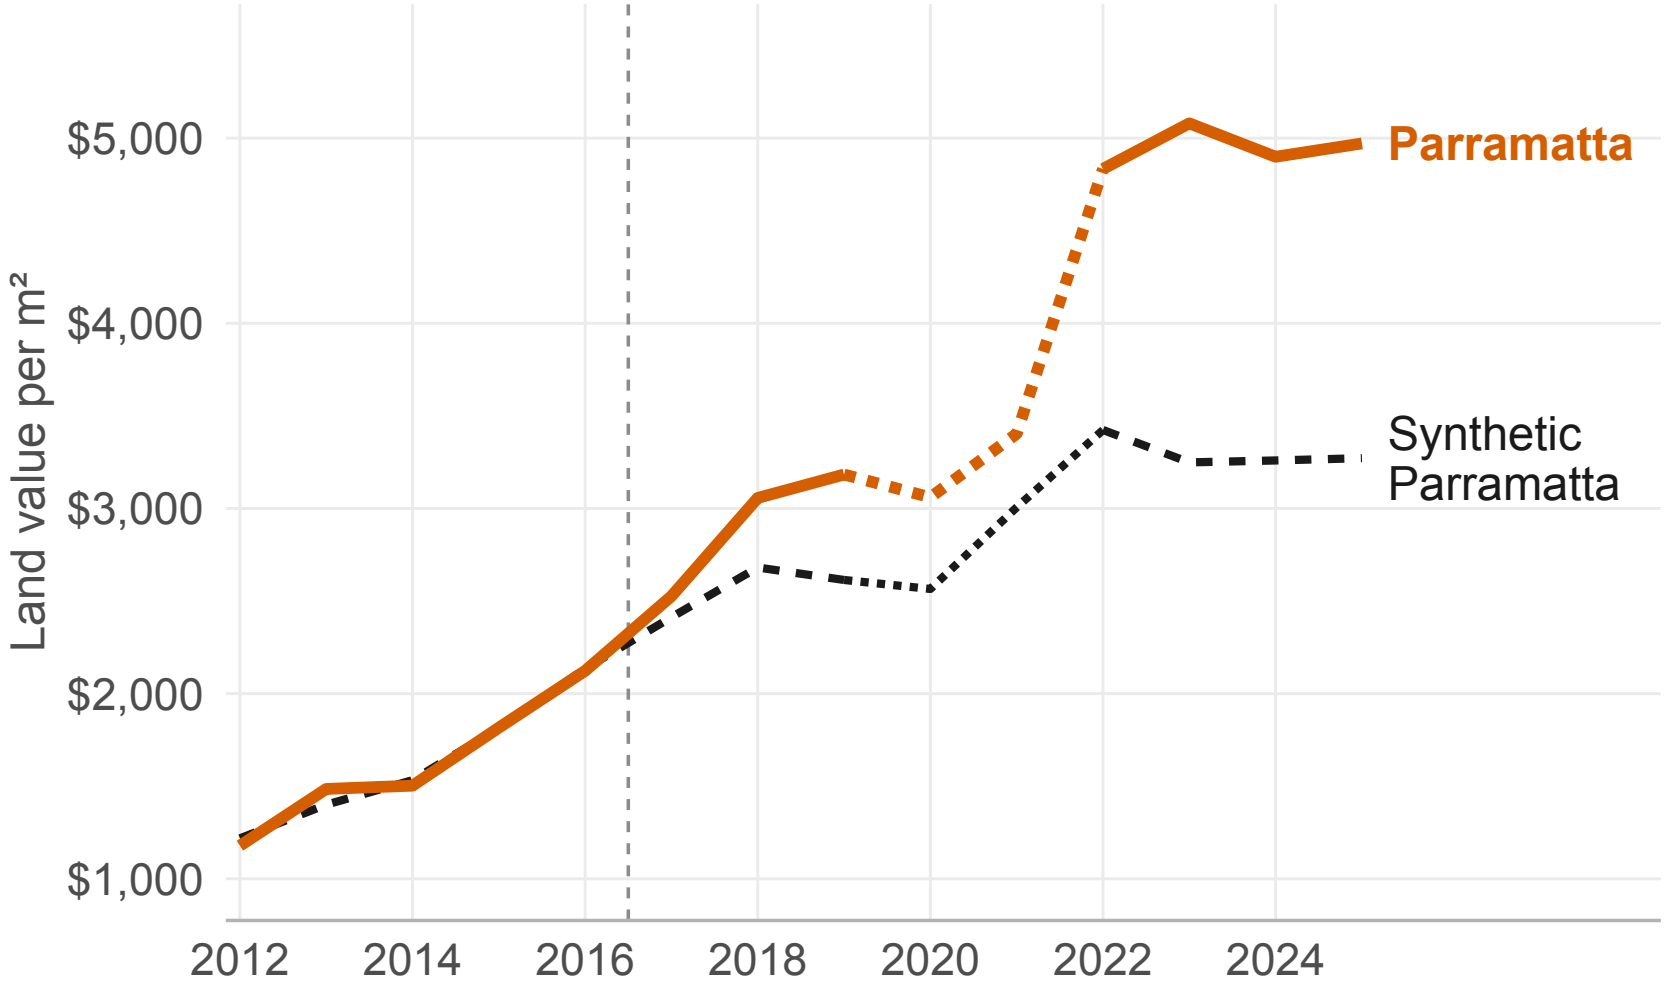

Synthetic control: four centres carry the weight

800 m circles over 2016 jobs per km^2; ■ = CBD. Weights from the 2012–16 fit.

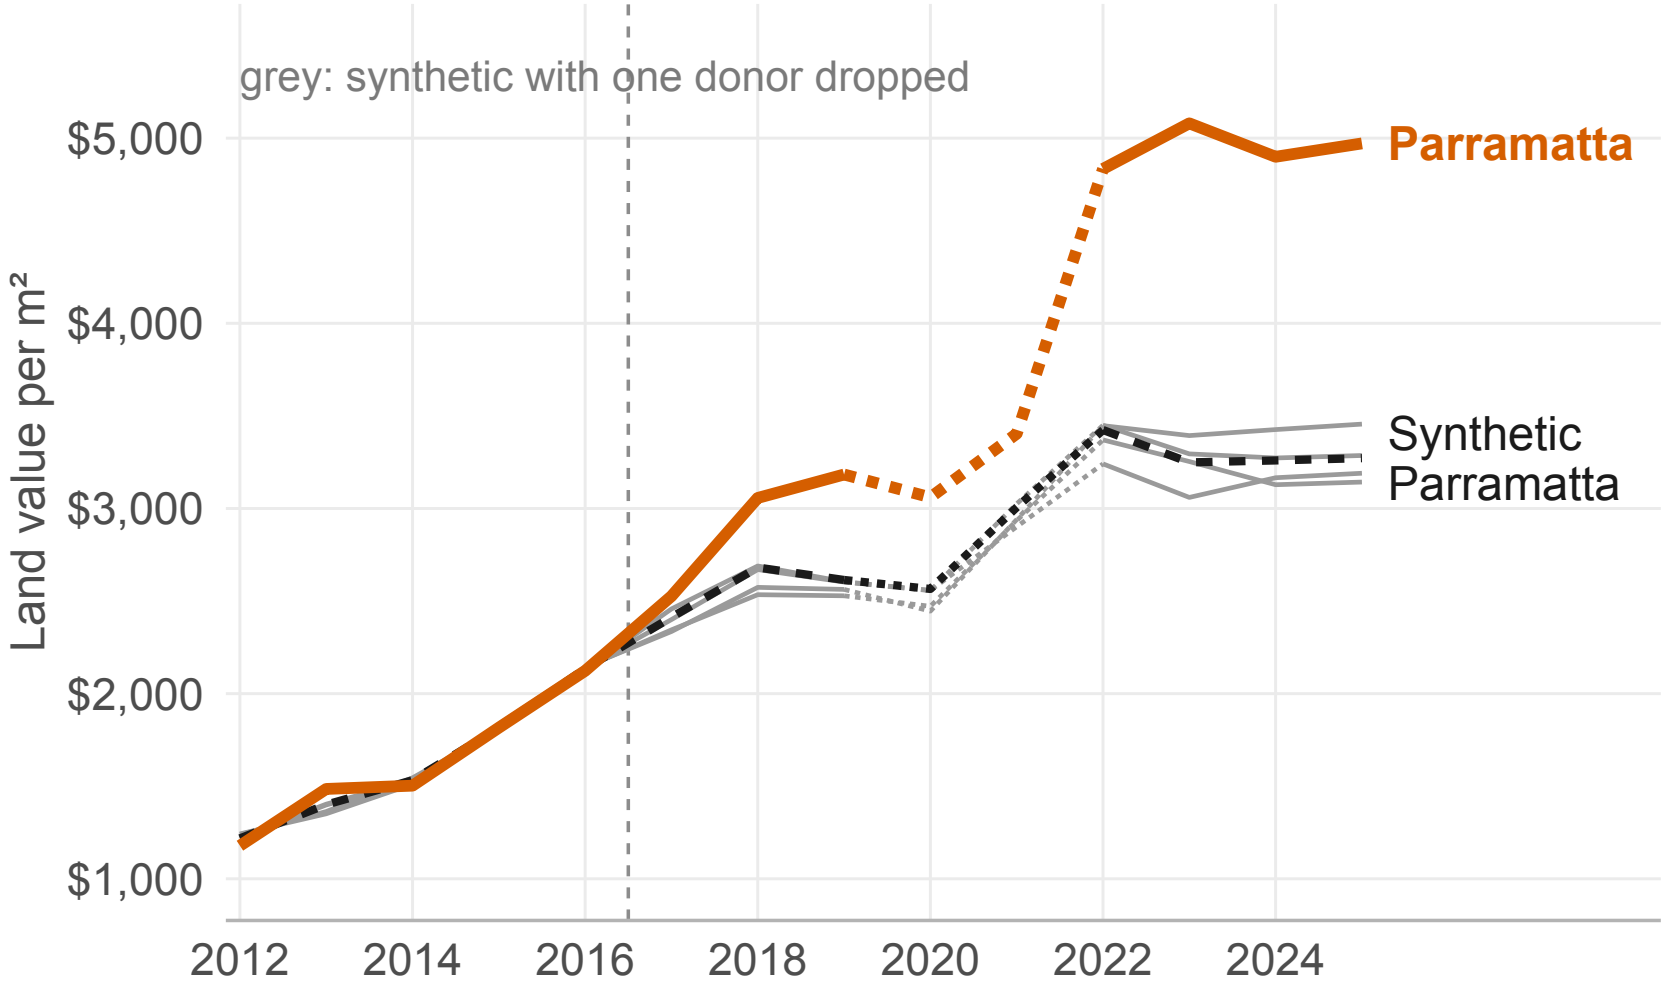

The screens →

Commercial land values pull away after the lease: +$1,700 per m^2

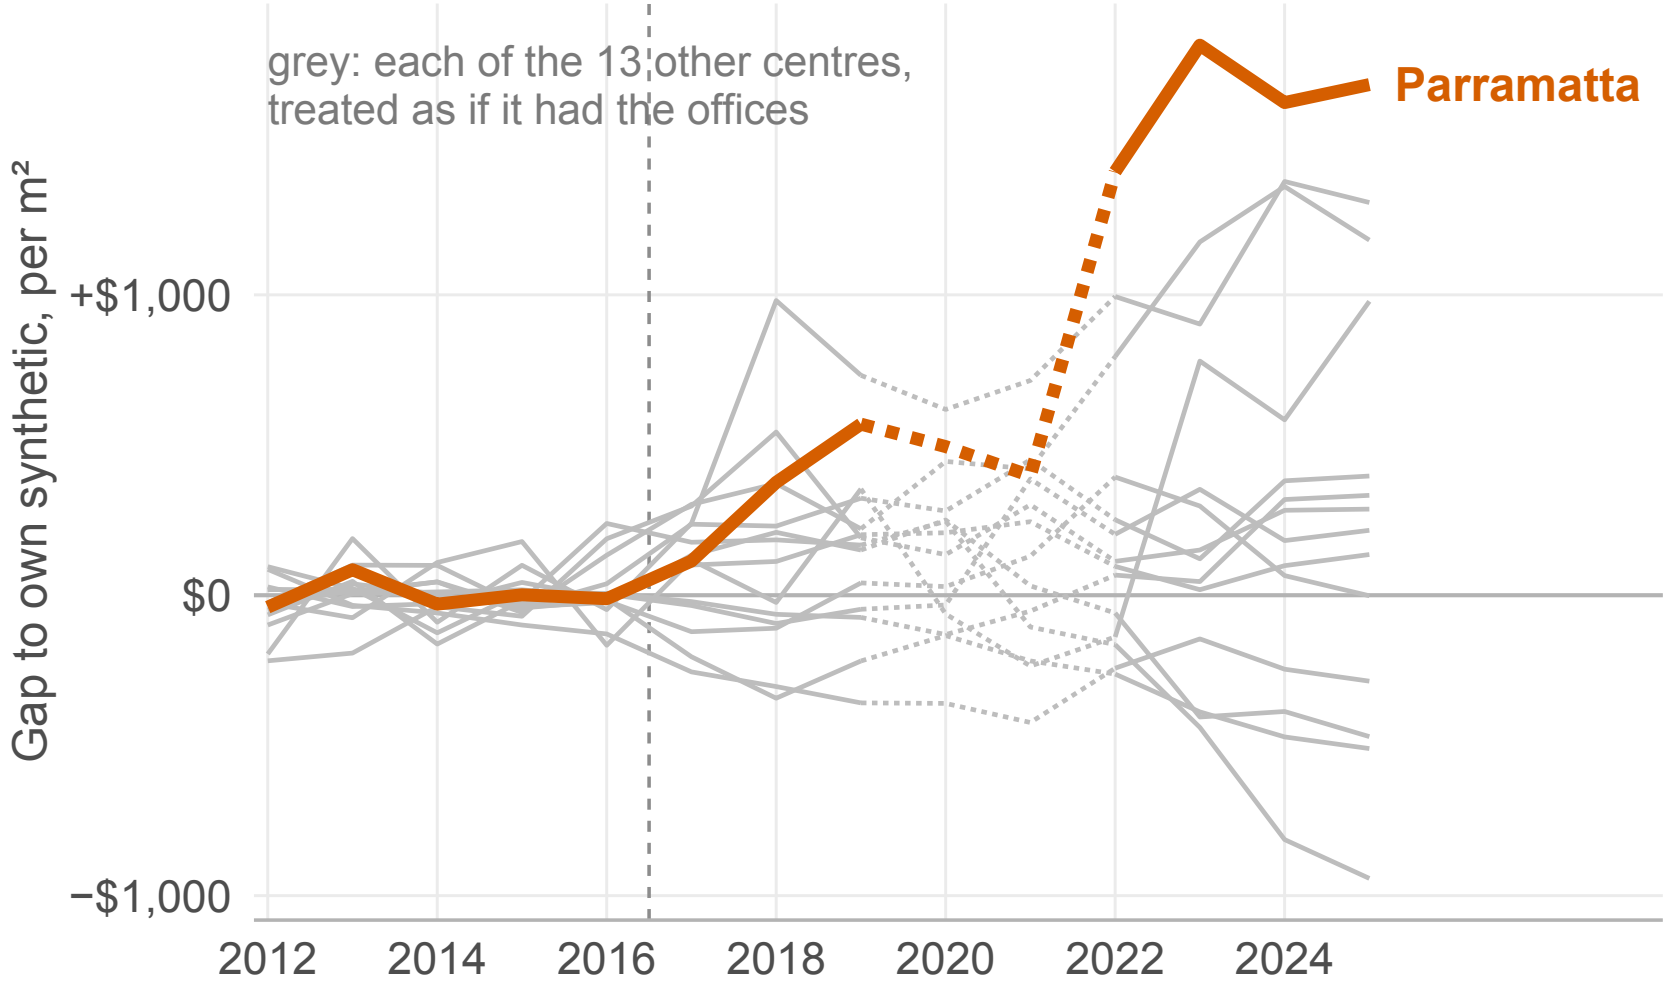

Land value per m^2 of commercial-zoned land (excl. industrial), same parcels throughout, 800 m circle. Dashed line: Dec 2016 lease.

Commercial land values pull away after the lease: +$1,700 per m^2

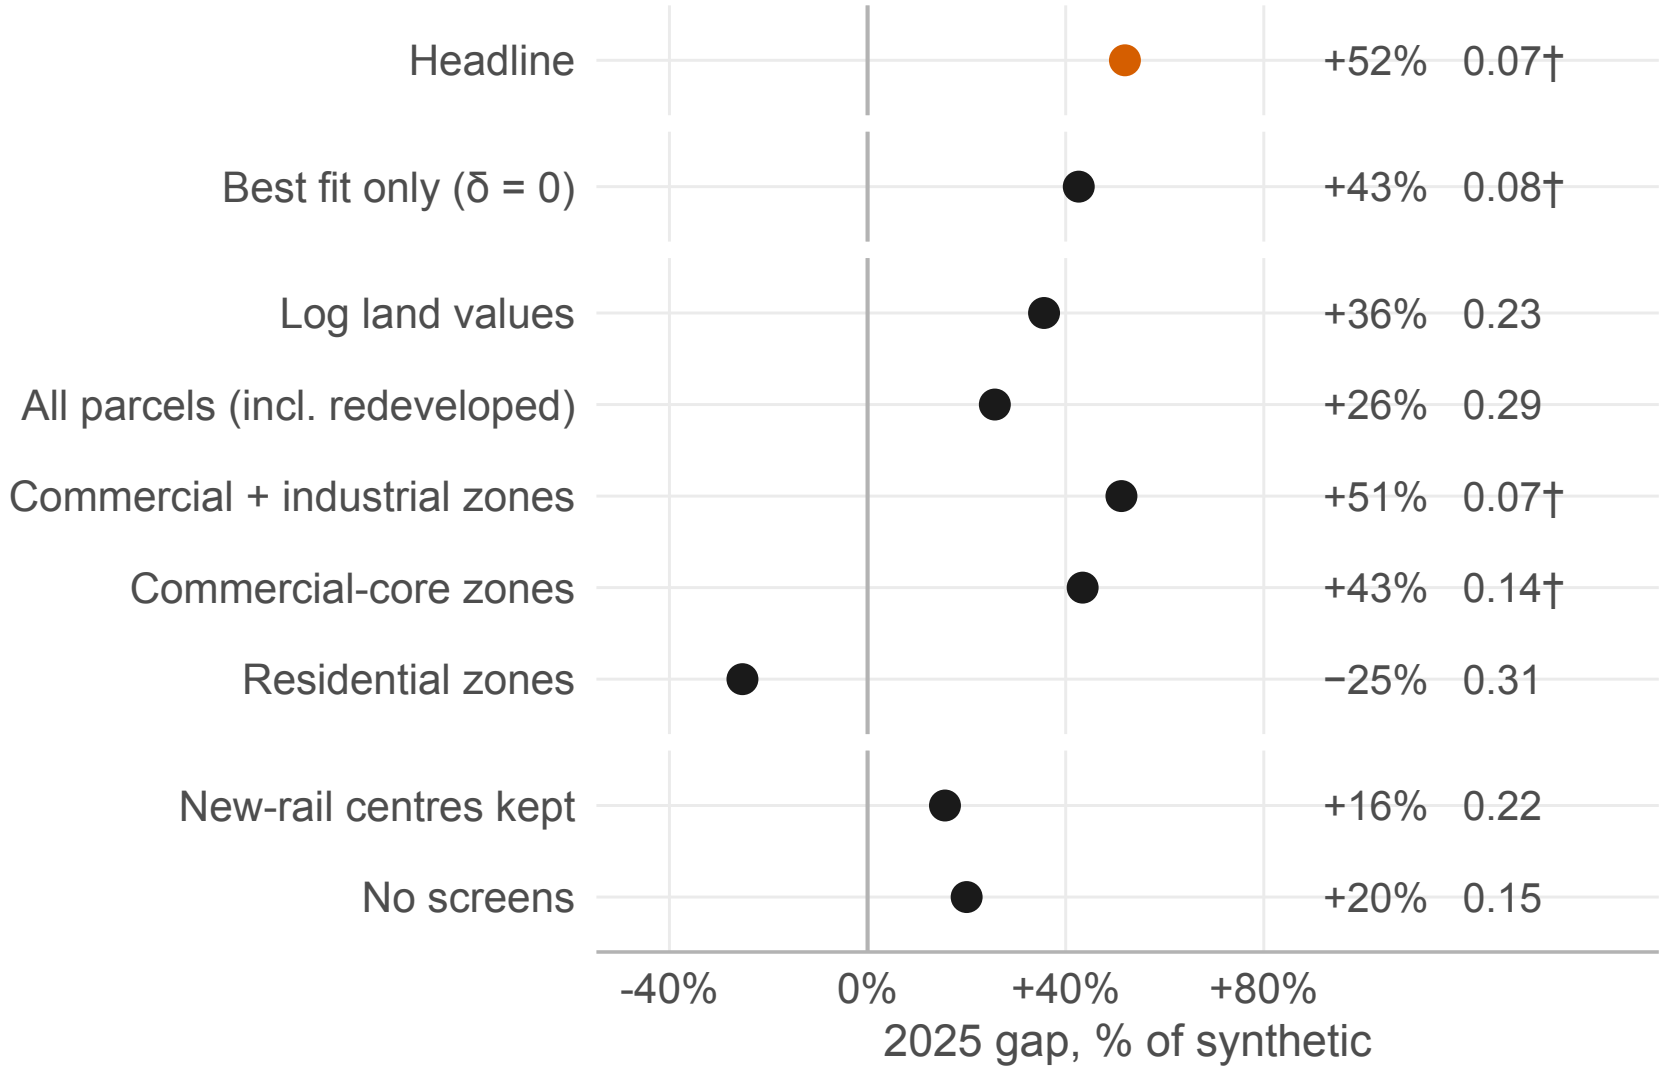

Land value per m^2 of commercial-zoned land (excl. industrial), same parcels throughout, 800 m circle. Dashed line: Dec 2016 lease. Grey: the synthetic rebuilt with each weighted donor dropped in turn.

No other centre shows a gap this large

Each grey line: one donor centre, with its own synthetic control, as if it had received the offices (the 13 that fit their own pre-period well). Parramatta's post-2017 gap is the largest: $p = 1/14 = 0.07$.

The gap is robust to the outcome — less so to the donor screens

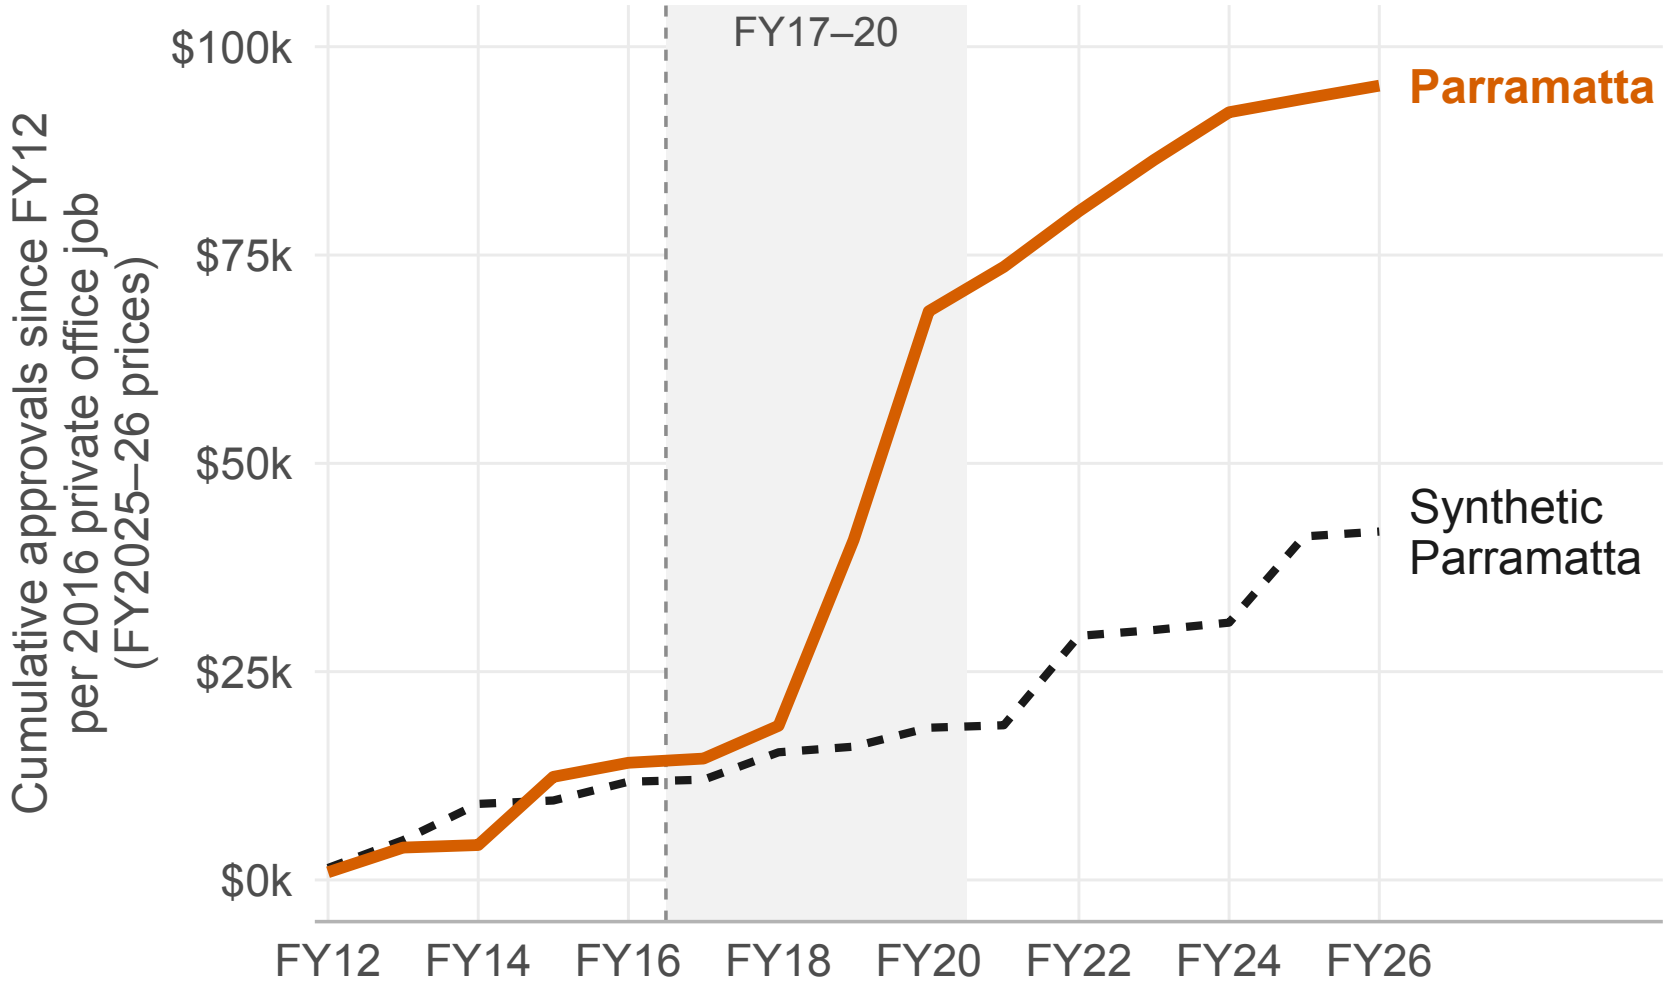

Right: 2025 gap (% of synthetic), placebo *p*; † = Parramatta's gap is the largest.

Second outcome: private office approvals

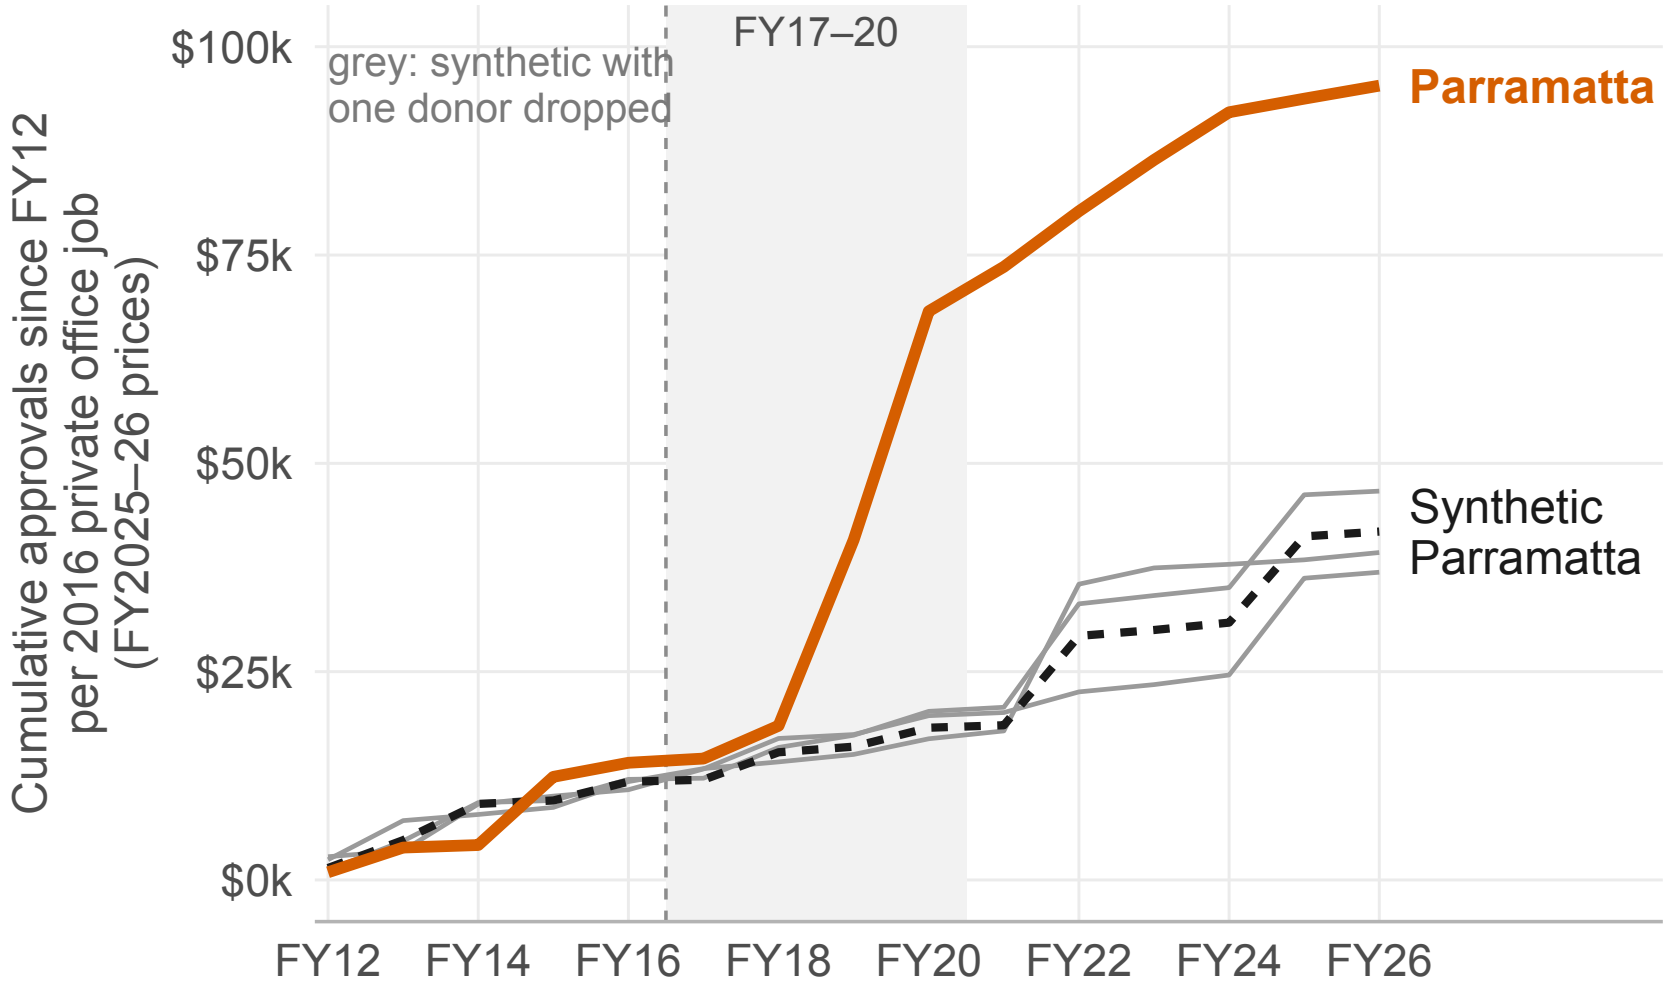

- **Data:** ABS building approvals: $ of office work by small area, monthly, 2011–26
- **Units:** regions with a stable ABS footprint; Parramatta $\approx 8.5\ \text{km}^2$
- **Private only:** ABS codes the *owner*, not the tenant
  - net out the government floors of the three leased towers
- **Outcome:** cumulative real approvals since FY2012, per 2016 private office job
- **Same estimator:** donors = the 10 regions most similar to Parramatta; fit FY2012–16; effect = gap opening over FY2017–20

Approvals pull away in FY2019–20: +$1,049**m**

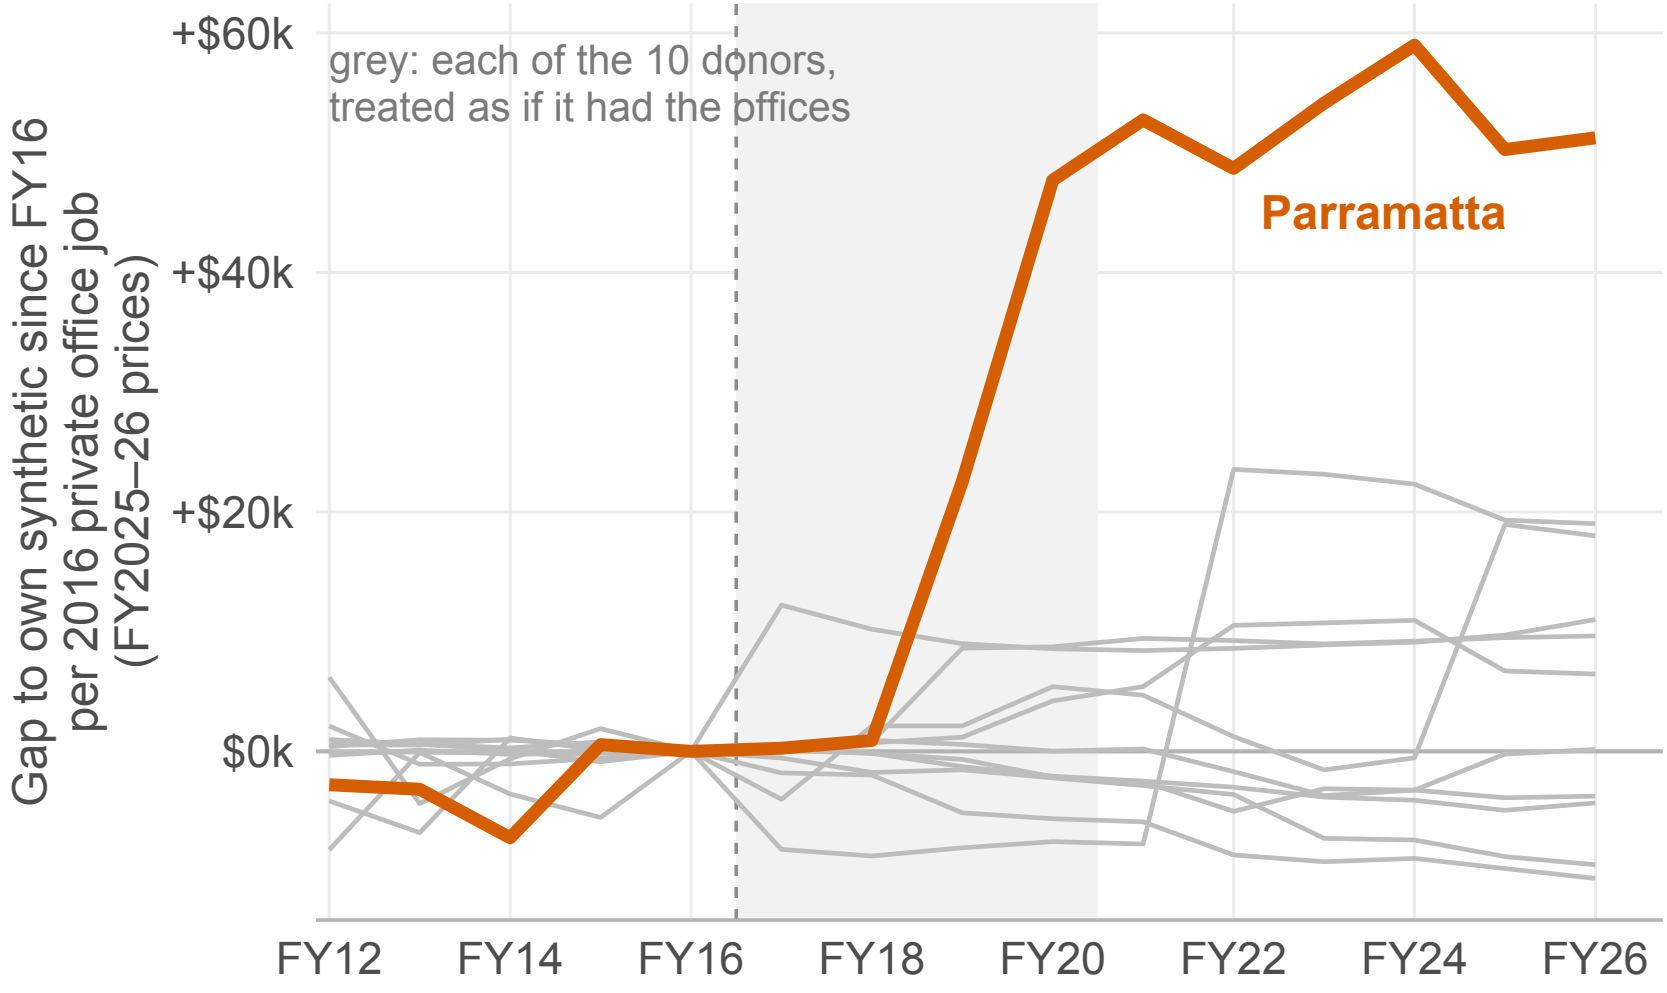

Cumulative real private office approvals (FY2025–26 prices) per 2016 private office job.
Pre-period error 38 % of Parramatta's level.

Approvals pull away in FY2019–20: +$1,049**m**

Cumulative real private office approvals (FY2025–26 prices) per 2016 private office job. Pre-period error 38 % of Parramatta's level. Grey: each weighted donor dropped; +$996m to +$1,079m.

No donor shows a gap close to Parramatta's

Gap to own synthetic, re-based at FY2016. Grey: each donor on its own pool. p = 1/11 = 0.09, the floor.

In jobs: room for about 8,300 office workers

jobs = gap ÷ (approvals per m^2 of consented GFA) × (NLA / GFA) ÷ (m^2 per worker)

Input	Central	Range	Source
Approvals per m^2 of consented GFA	6,645	5,520–7,650	Parramatta, FY17–20
NLA / consented GFA	0.93	0.86–0.95	owners' published NLAs
m^2 per worker	17.7	14.5–20.7	City of Sydney floorspace survey
Jobs per $1m	7.9	5.4–9.7	
The $1,049m gap, jobs	≈ **8,300**	5,700–10,200	sector m^2: 9,000–10,100

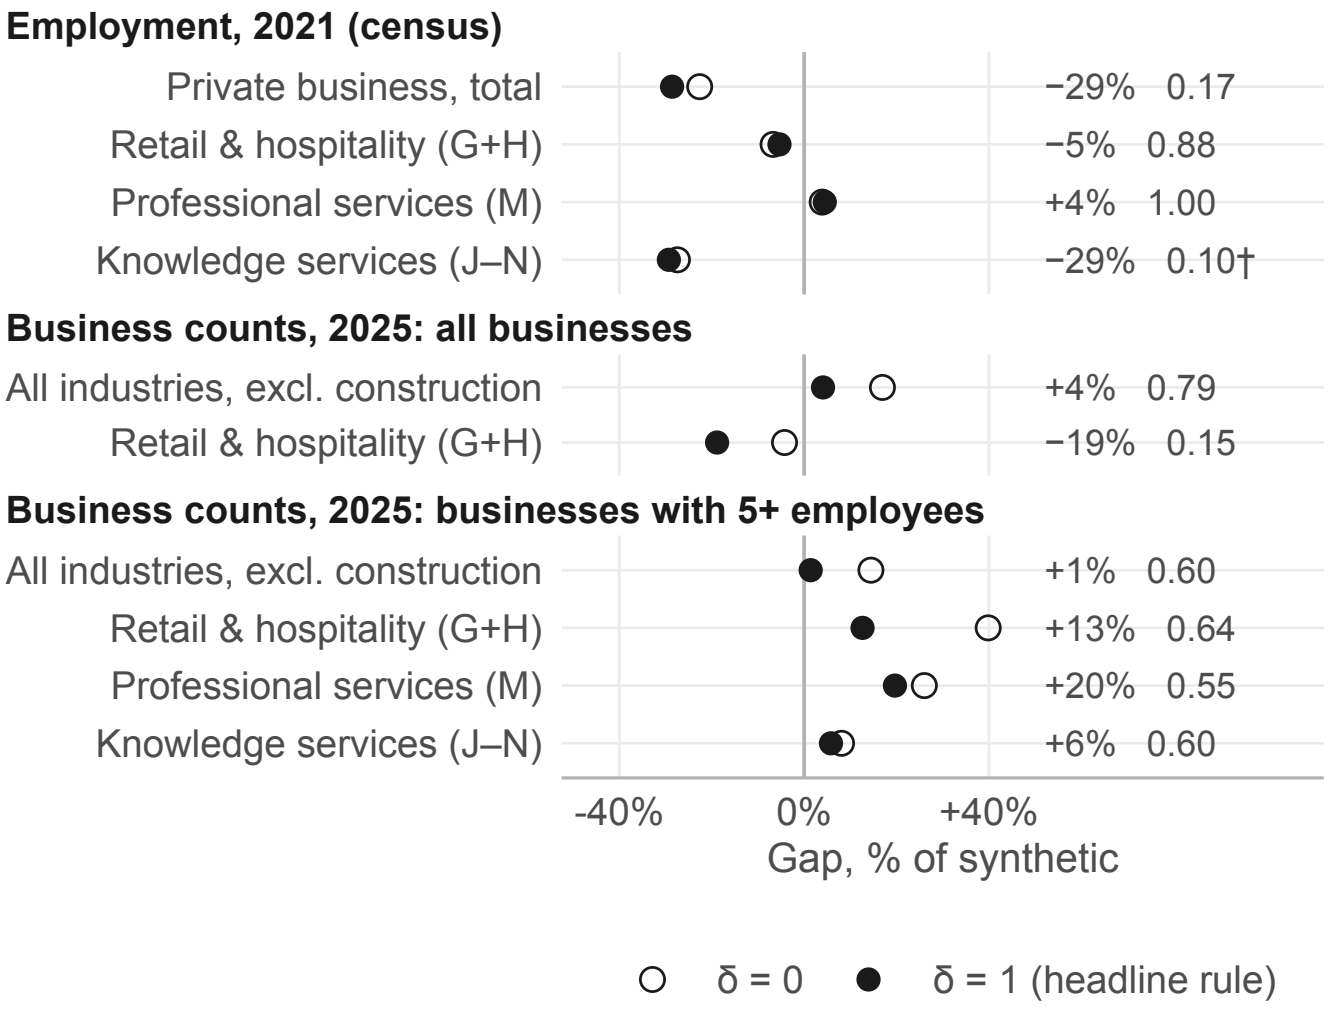

$ at FY2025–26 prices. GFA: gross floor area as consented, which leaves out lifts, stairs, plant and parking. NLA: net lettable area, the rentable floor. Approvals per m^2 exceed construction cost ($5,567) through fit-outs and repeat approvals; range: the cost spread across five towers.

- **Capacity**, not realised jobs: consents, not floor space
- Mostly delivered after census 2021: 2026 is the test

Robustness →

Private jobs: no detectable response yet

Private jobs: no detectable response yet

Right: $\delta = 1$ gap, placebo p. Employment: 2021 Census (lockdown; before 6 PSQ). Business counts: ABS register (no government), 2025.

Dynamic version: slow re-sorting, forward-looking land prices

- Each 5-year period a share θ of workers re-choose home and job:

$$L_{ij,t+1} = (1 - \theta)\, L_{ij,t} + \theta\, L_t\, m_{ij,t+1}$$

  $L_{ij,t}$: workers living in i, working in j; m_{ij}: choice shares, given expected future utility

- Builders price floorspace off the *whole* future path of rents; floorspace depreciates

- Land values capitalise the policy on announcement (Dec 2016)

$\rightarrow$ *the static model is the dynamic model's long run*

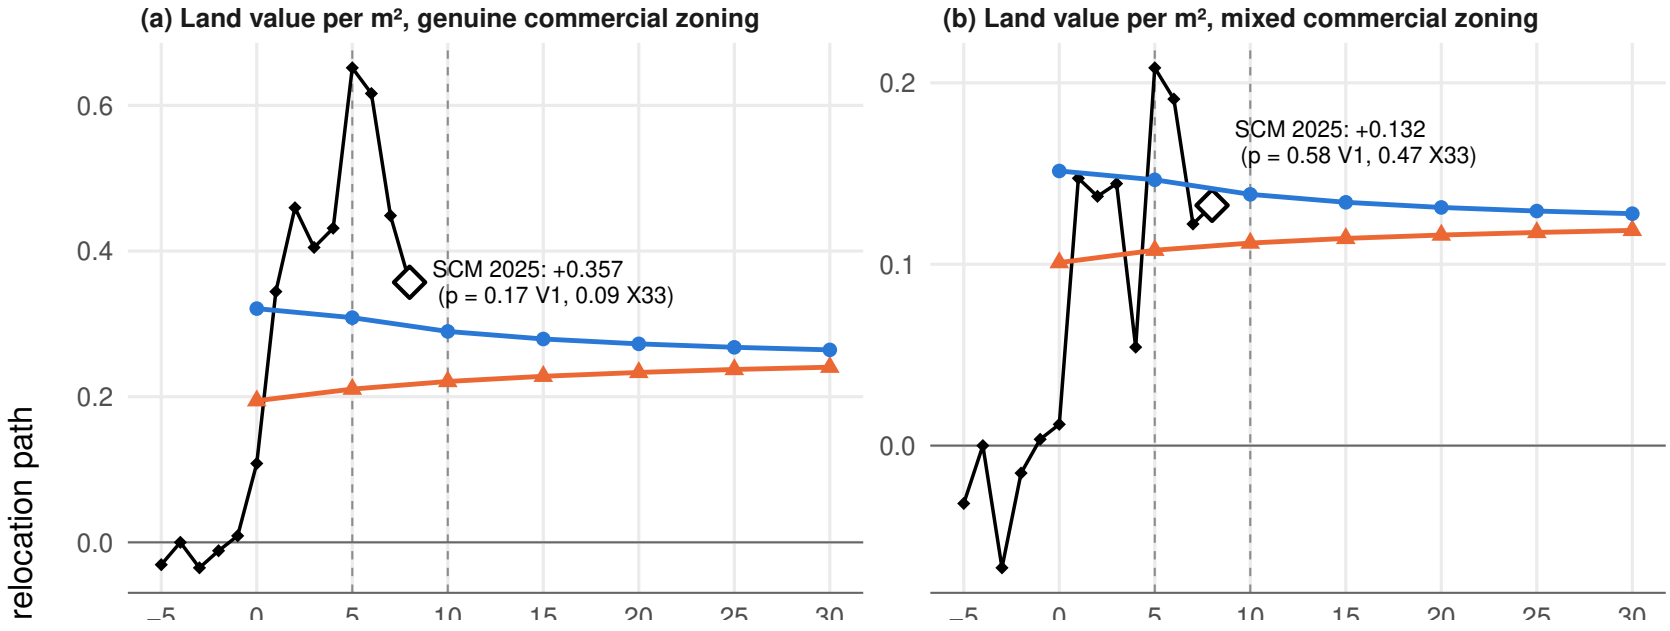

Calibration: Half of workers re-choose home and job every five years

Parameter	Value	Source
Re-choice rate θ, per 5 yrs	0.5	ACLD job moves
Depreciation, per 5 yrs	0.145	Baum-Snow & Han
Housing share, h / l	.28 / .32	expenditure surveys
Commuting decay, h / l	.112 / .134	gravity by education
Public wage, h / l	1.07 / 0.78	2016 Census

$\rightarrow$ *shock:* +9,700 *public jobs by 2021,* +4,200 *more in 2022*

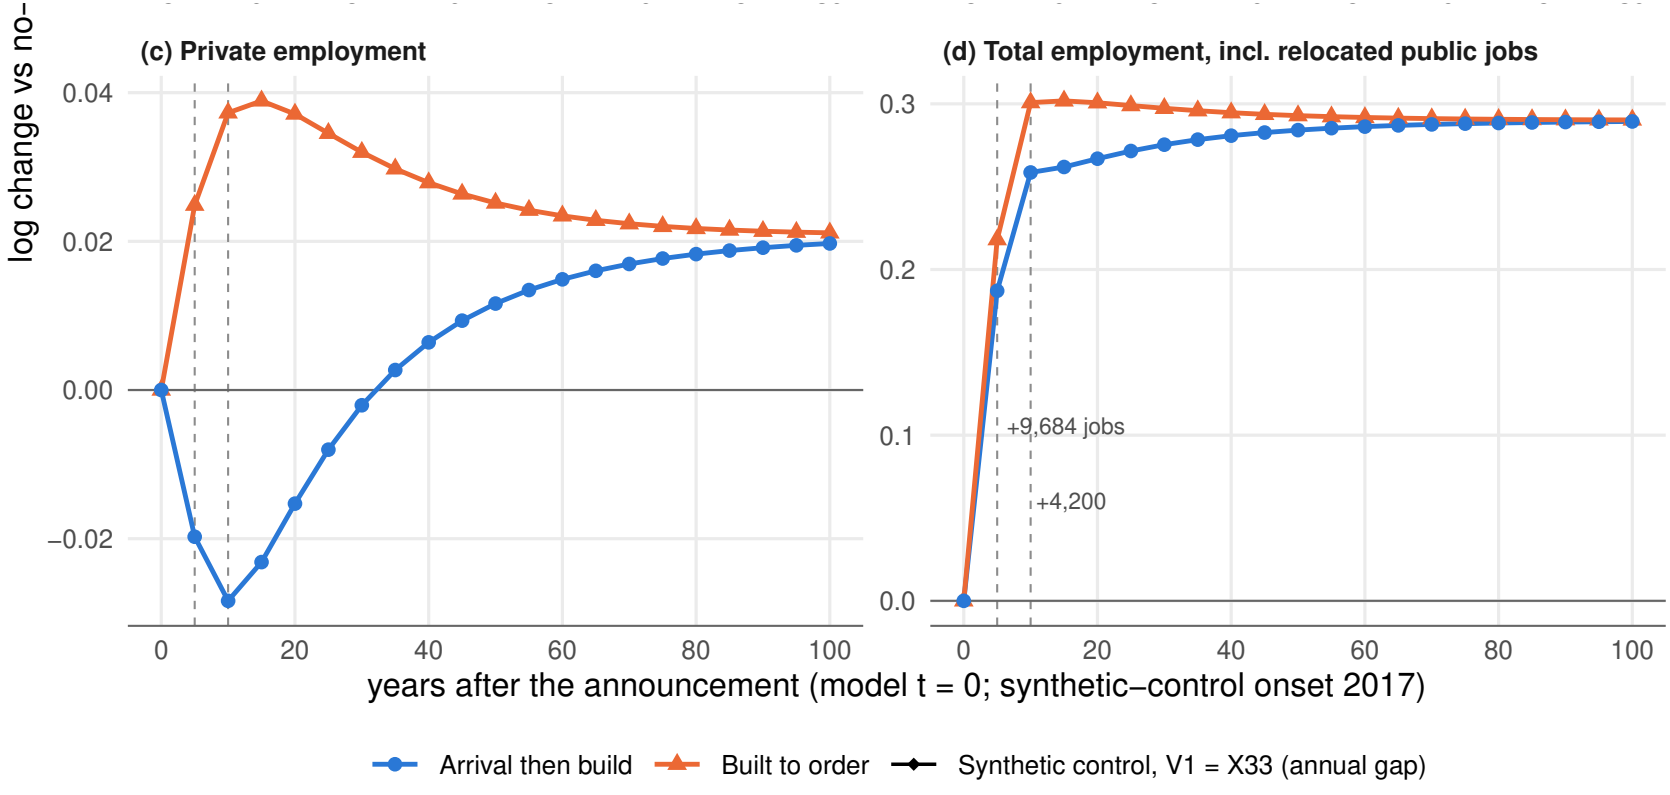

h/l: graduates / non-graduates. Public wage relative to the private wage of the same type. The dynamic runs use an earlier Fréchet dispersion (6.49) and housing shares (0.27/0.33) than the static headline.

The dynamic model: prices jump at once, private jobs follow slowly

Log change in land value vs. no relocation; years after the Dec 2016 announcement. Black: an earlier synthetic control (log, all commercial zones). Headline design above, in logs: +0.31.

The dynamic model: prices jump at once, private jobs follow slowly

Log change in private and total employment within 800 m of Parramatta Square vs. no relocation.

Conclusion

- Lopsidedness is costly: a central CBD $\Rightarrow$ output +11%, welfare +2.5%, most for graduates
- In so far as the policy is locally successful, it reduces citywide output but may help non-graduates
- Cause: concentrating employment in the CBD's graduate-intensive technology helps graduates; dispersing away from there helps non-graduates
- Data: business land values +52% vs a synthetic control; private jobs not (yet) following
- Dynamic model: prices capitalise at once, jobs follow slowly

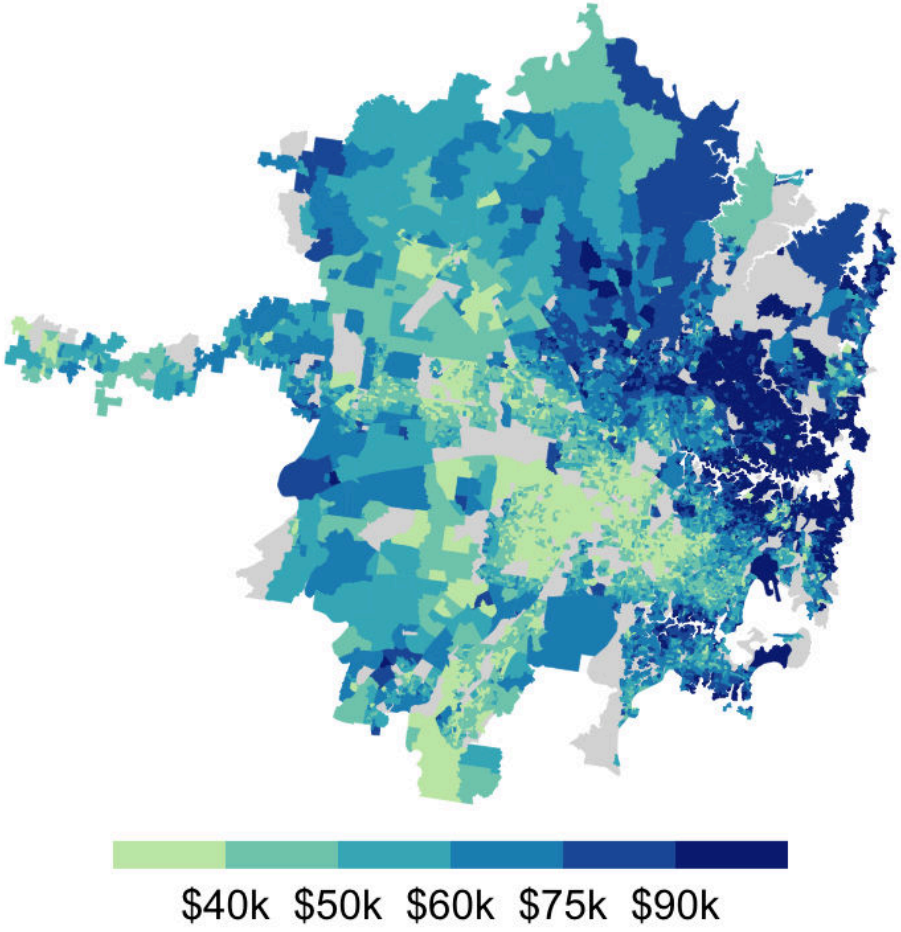

$\rightarrow$ *next: the 2026 Census, and ϕ_P from the land-value response*

Backup

Which half of the spillover field drives the result

Change in non-graduate welfare (%), relative to the move with no spillover ($\phi_P^h = \phi_P^l = 0$)

	$\phi_P^h = 1,\ \phi_P^l = 0$	$\phi_P^h = 0,\ \phi_P^l = 1$
Gain at Parramatta only	+0.015	+0.029
Loss at the CBD only	+0.026	−0.002
Both (the full move)	+0.041	+0.026

Each row counts the public jobs' spillover only where they arrive, only where they leave, or both. The floorspace move is the same in every cell.

← Back Backup

The donor screens

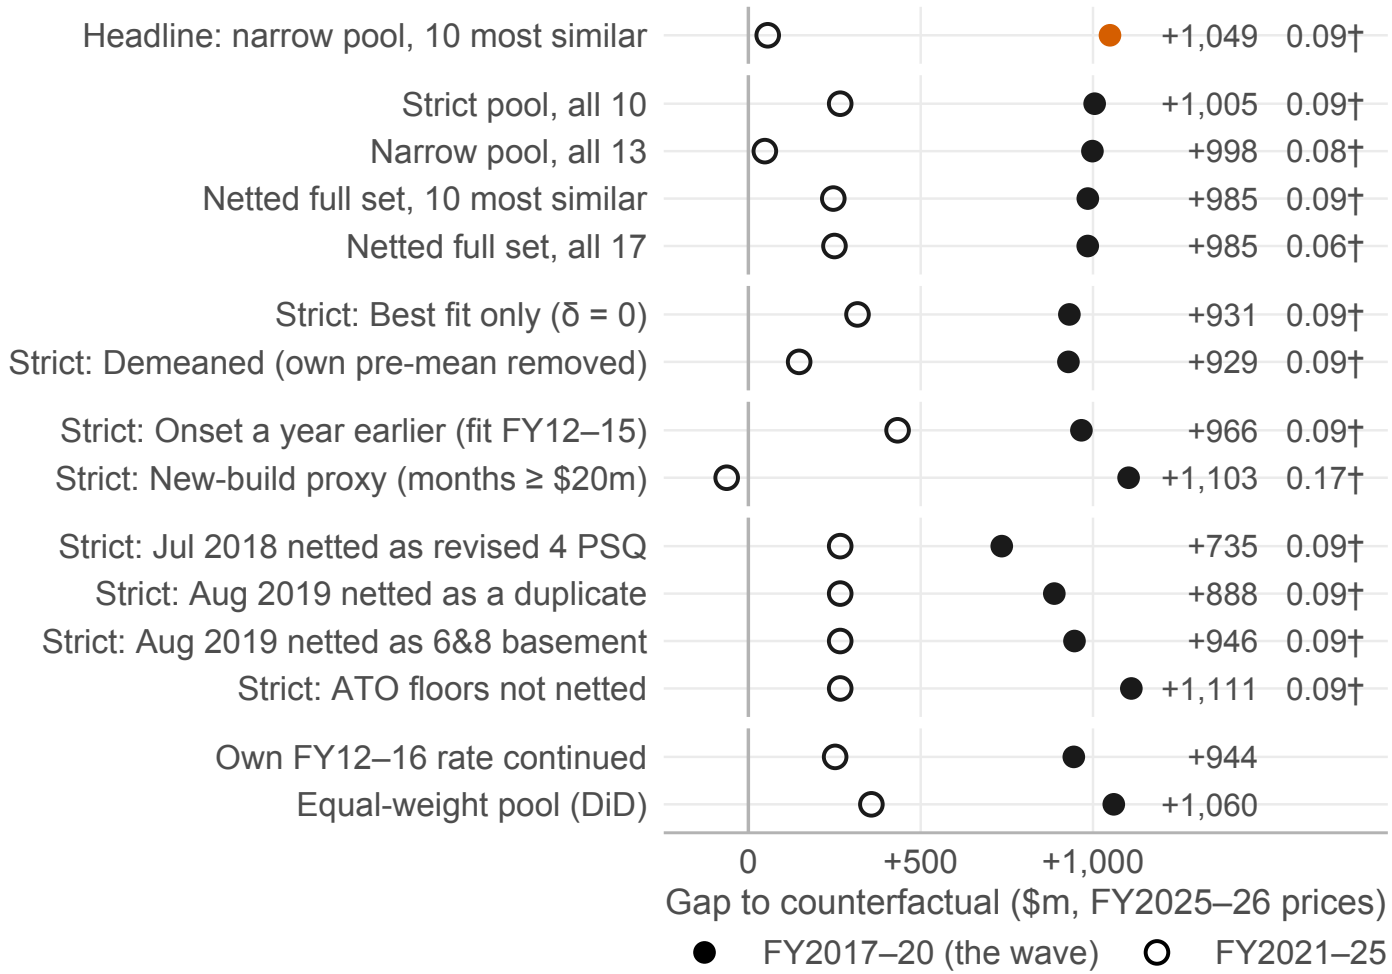

Public-jobs shock. For each centre, the 2016–21 change in government jobs as a share of its 2016 jobs, minus Sydney's (+2.25%). Screened if at least 20% of Parramatta's (+21.1%):

Centre	change in government jobs	net of Sydney
Parramatta	+9,684	+21.1%
St Leonards	+4,303	+14.1%
Campbelltown	+422	+6.1%
Liverpool	+1,287	+5.7%

New rail. A new Metro station within 1.2 km, opened 2017–25: North Sydney (Victoria Cross, 2024); Bella Vista, Norwest and Castle Hill (2019).
Tie-break ($\delta = 1$). Minimise $\sum_j w_j d_j$ (d_j: distance to Parramatta in pre-2017 characteristics) subject to the pre-period fit within 1% of the best fit; the same rule for every placebo.

← Back Backup

Approvals: robust in the wave, fragile after it

Right: FY2017–20 gap ($m), placebo *p*; † = Parramatta largest. Rule, series, netting rows: strict pool.
